Binary trees

Binary trees with ≤ 5 leaves:

Pattern containment

Patterns are contiguous. For example, let $t =$ .

Small binary trees containing...

0 copies of t : 

1 copy of t : 

2 copies of t : 

3 copies of t : 

Outline

- 1 Definitions
- 2 Enumeration**
- 3 Equivalence

4-leaf tree patterns

4-leaf tree patterns: 

- $t =$ . A “typical” tree avoiding t looks like

$$a(1) = 1; a(n) = 2^{n-2} \text{ for } n \geq 2.$$

- $t =$ . A “typical” tree avoiding t looks like

$$a(1) = 1; a(n) = 2^{n-2} \text{ for } n \geq 2.$$

These two patterns are equivalent.

The remaining 4-leaf pattern

- $t =$ . Some trees avoiding t :

Donaghey and Shapiro showed that $a(n) = M_{n-1}$.

Generating functions algorithm

$$\text{Let } \text{Av}_t(x) = \sum_{T \text{ avoids } t} x^{\text{number of vertices in } T} = \sum_{n=0}^{\infty} a(n)x^n.$$

Consider the tree pattern

$$t = \begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \end{array} = \begin{array}{c} \bullet \\ \wedge \\ t_l t_r \end{array}, \quad \text{where } t_l = \bullet \text{ and } t_r = \begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \end{array}.$$

For a given tree pattern p , let

$$\text{weight}(p) := \sum_{T \text{ matches } p \text{ and avoids } t} x^{\text{number of vertices in } T}.$$

Begin with $\text{weight}(\bullet) = x + \text{weight}(\begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \end{array})$; rewrite $\text{weight}(\begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \end{array})$ by

$$\text{weight}\left(\begin{array}{c} \bullet \\ \wedge \\ p_l p_r \end{array}\right) = x \cdot (\text{weight}(p_l) \cdot \text{weight}(p_r) - \text{weight}(p_l \cap t_l) \cdot \text{weight}(p_r \cap t_r)).$$

System of polynomial equations

$$\begin{aligned}\text{weight}(\text{⌘}) &= x \cdot (\text{weight}(\cdot) \cdot \text{weight}(\cdot) - \text{weight}(\cdot \cap \cdot) \cdot \text{weight}(\cdot \cap \text{⌘})) \\ &= x \cdot (\text{weight}(\cdot)^2 - \text{weight}(\cdot) \cdot \text{weight}(\text{⌘}))\end{aligned}$$

$$\begin{aligned}\text{weight}(\text{⌘}) &= x \cdot (\text{weight}(\cdot) \cdot \text{weight}(\text{⌘}) - \text{weight}(\cdot \cap \cdot) \cdot \text{weight}(\text{⌘} \cap \text{⌘})) \\ &= x \cdot (\text{weight}(\cdot) \cdot \text{weight}(\text{⌘}) - \text{weight}(\cdot) \cdot \text{weight}(\text{⌘}))\end{aligned}$$

$$\begin{aligned}\text{weight}(\text{⌘}) &= x \cdot (\text{weight}(\text{⌘}) \cdot \text{weight}(\cdot) - \text{weight}(\text{⌘} \cap \cdot) \cdot \text{weight}(\cdot \cap \text{⌘})) \\ &= x \cdot (\text{weight}(\text{⌘}) \cdot \text{weight}(\cdot) - \text{weight}(\text{⌘}) \cdot \text{weight}(\text{⌘}))\end{aligned}$$

$$\begin{aligned}\text{weight}(\text{⌘}) &= x \cdot (\text{weight}(\text{⌘}) \cdot \text{weight}(\text{⌘}) - \text{weight}(\text{⌘} \cap \cdot) \cdot \text{weight}(\text{⌘} \cap \text{⌘})) \\ &= x \cdot (\text{weight}(\text{⌘}) \cdot \text{weight}(\text{⌘}) - \text{weight}(\text{⌘}) \cdot \text{weight}(\text{⌘}))\end{aligned}$$

No new variables. Eliminate the four auxiliary variables to obtain

$$x^3 \text{Av}_t(x)^2 - (x^2 - 1)^2 \text{Av}_t(x) - x(x^2 - 1) = 0.$$

The algorithm terminates:

Since $\text{depth}(p \cap p') \leq \max(\text{depth}(p), \text{depth}(p'))$ and there are only finitely many trees shallower than t , there are finitely many variables.

Final step:

Eliminating all variables except x and $\text{weight}(\cdot) = Av_t(x)$ entails computing a Gröbner basis for the system, which may take time.

Theorem

$Av_t(x)$ is algebraic.

And the algebraic equation can be constructed mechanically.

Generalizations

The enumerating generating function

$$\text{En}_t(x, y) = \sum_T x^{\text{number of vertices in } T} y^{\text{number of copies of } t \text{ in } T}$$

is algebraic.

Conjecture

If s and t are avoiding-equivalent, then they are also enumerating-equivalent.

The generating function that enumerates trees with respect to multiple patterns is also algebraic.

5-leaf equivalence classes

A computer implementation establishes all equivalence classes for binary trees up to 8 leaves.

For $m = 1, 2, 3, \dots$, there are 1, 1, 1, 2, 3, 7, 15, 44, \dots equivalence classes of m -leaf binary trees.

For 5-leaf tree patterns...

 and  form an equivalence class.

 and  form an equivalence class.

The other 10 tree patterns are equivalent:

6-leaf equivalence classes

Isolated trees:

- 2 Enumeration
- 3 Equivalence**

Analogy to avoidance in words

Can we easily tell when s and t are equivalent?

How many length- n words on an alphabet avoid a certain (contiguous) subword?

The answer depends only on the self-overlap lengths of the subword.

Equivalence classes of length-4 words on the alphabet $\{0, 1\}$:

equivalence class	self-overlap lengths
$\{0001, 0011, 0111, 1000, 1100, 1110\}$	$\{4\}$
$\{0010, 0100, 0110, 1001, 1011, 1101\}$	$\{1, 4\}$
$\{0101, 1010\}$	$\{2, 4\}$
$\{0000, 1111\}$	$\{1, 2, 3, 4\}$

Self-overlaps

For trees, one might hope for the same criterion:

“ s and t are equivalent precisely when their self-overlaps coincide.”

The self-overlap lengths seem to be preserved under equivalence.

But the statement is not true in general. Counterexample:

Both classes have overlap lengths $\{1, 1, 2, 2, 5\}$.

Bijjective proofs

Given two equivalent tree patterns s and t , can we find a bijective proof of the equivalence?

For example,  and  are equivalent.

Let T avoid . Idea: Replace all instances of  with . How?

What order? top-down.

For example:

Inverse

The inverse map is a *bottom-up replacement* with the inverse replacement rule:

For example:

Searching for bijections

Generally, we may individually try all $m!$ permutations of leaves.

Permutations whose replacements prove equivalence for pairs of 5-leaf trees:

	t_2	t_3	t_4	t_6	t_7	t_8	t_9	t_{11}	t_{12}	t_{13}
t_2	—	14235		43125						
t_3		—	12534	31245					51234	
t_4		12453	—			41235				
t_6				—	12534	45123				
t_7				12453	—		45123			
t_8				34512		—	31245			
t_9					34512	23145	—			
t_{11}					13452			—	31245	
t_{12}		23451					12453	23145	—	
t_{13}							14532		13425	—

Conjecture

Not every pair of equivalent trees can be shown equivalent by such a bijection. However, the following appears to hold.

Conjecture

Two binary tree patterns s and t are equivalent if and only if there is a sequence of

- *top-down replacements,*
- *bottom-up replacements, and*
- *left-right reflections*

that produces a bijection from binary trees avoiding s to binary trees avoiding t .

The conjecture is true for tree patterns of ≤ 7 leaves.

Open questions

What is the growth rate of the sequence $1, 1, 1, 2, 3, 7, 15, 44, \dots$ that counts the equivalence classes of m -leaf binary tree patterns for $m = 1, 2, 3, \dots$?

Is there a simple characterization of the permutations of leaves that establish the equivalence of s and t ?

Is there a simple characterization of the binary tree patterns that are equivalent to t ?

More recent work

2010 REU students at Valparaiso University:

Nathan Gabriel, Katie Peske, and Sam Tay classified ternary tree patterns with ≤ 9 leaves and introduced a representation of trees as sets of words that provides a new class of bijections.

2011 REU students:

Mike Dairyko, Samantha Tyner, and Casey Wynn are studying avoidance of non-contiguous binary tree patterns.

Work in progress. . .
